- Summary and resources

AZ-305: Design Identity, Governance, and Monitoring Solutions (25-30%)

Design Authentication and Authorization Solutions

- Recommend a solution for securing resources with role-based access controls
- Recommend an identity management solution
- Recommend a solution for securing identities

Design Identities and Access for Applications:

- Recommend a solution that securely stores passwords and secrets
- Recommend solutions to allow applications to access Azure resources
- Recommend a solution for integrating applications into Azure AD
- Recommend a user consent solution for applications
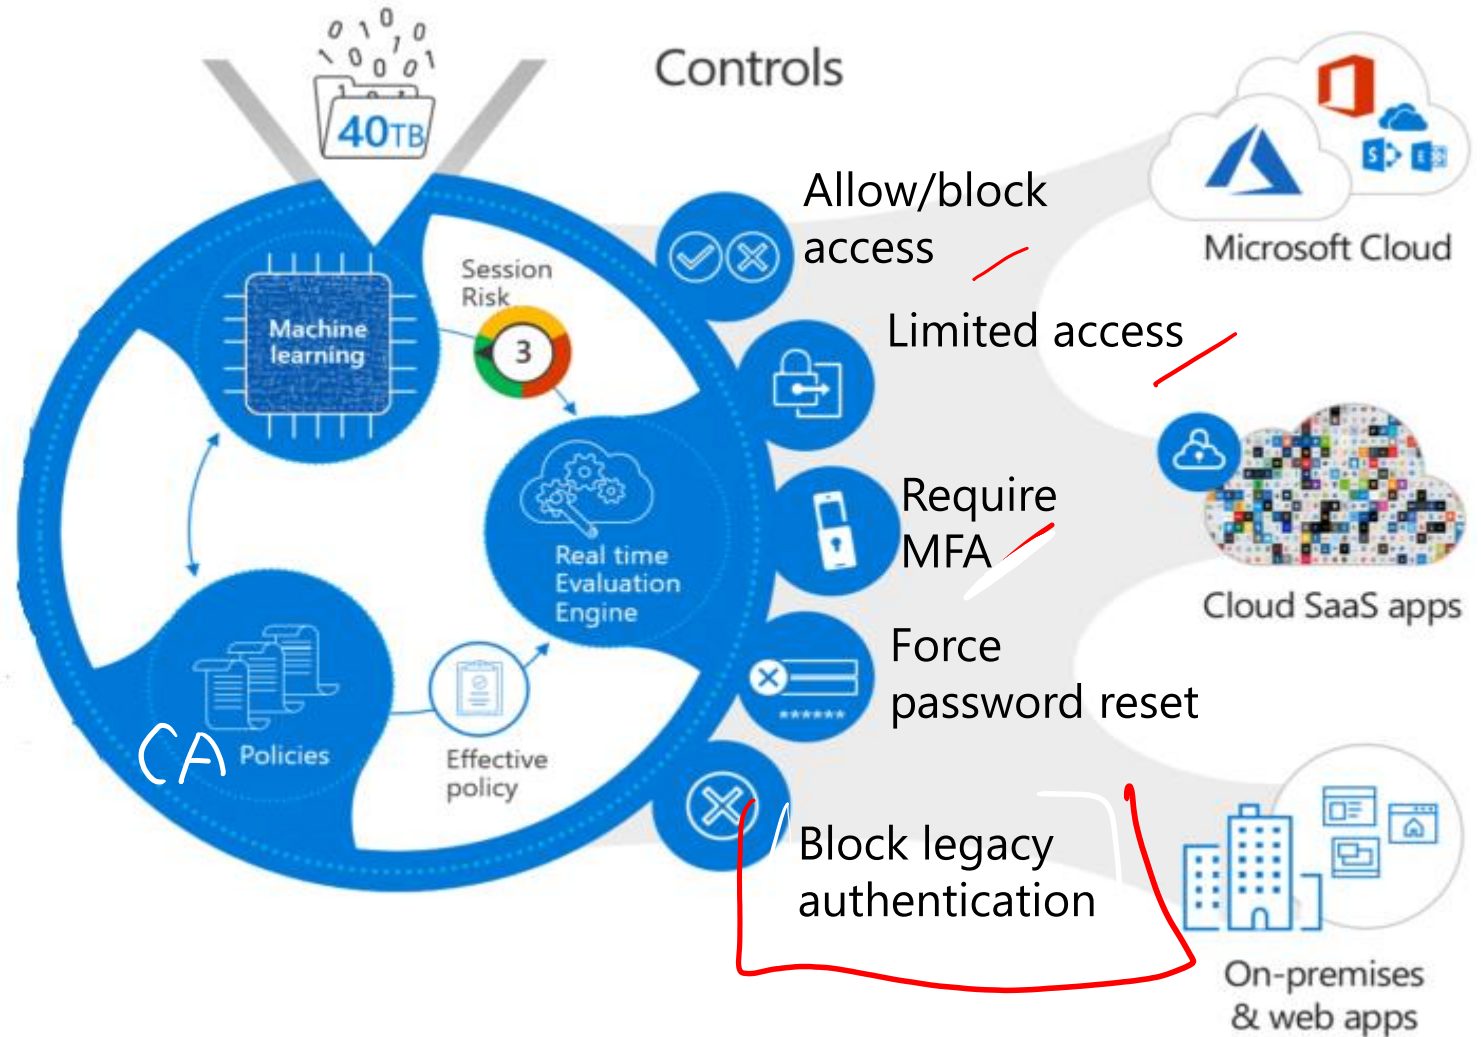

Design for identity and access management

Follow the Zero Trust model guidelines

Never trust, always verify.

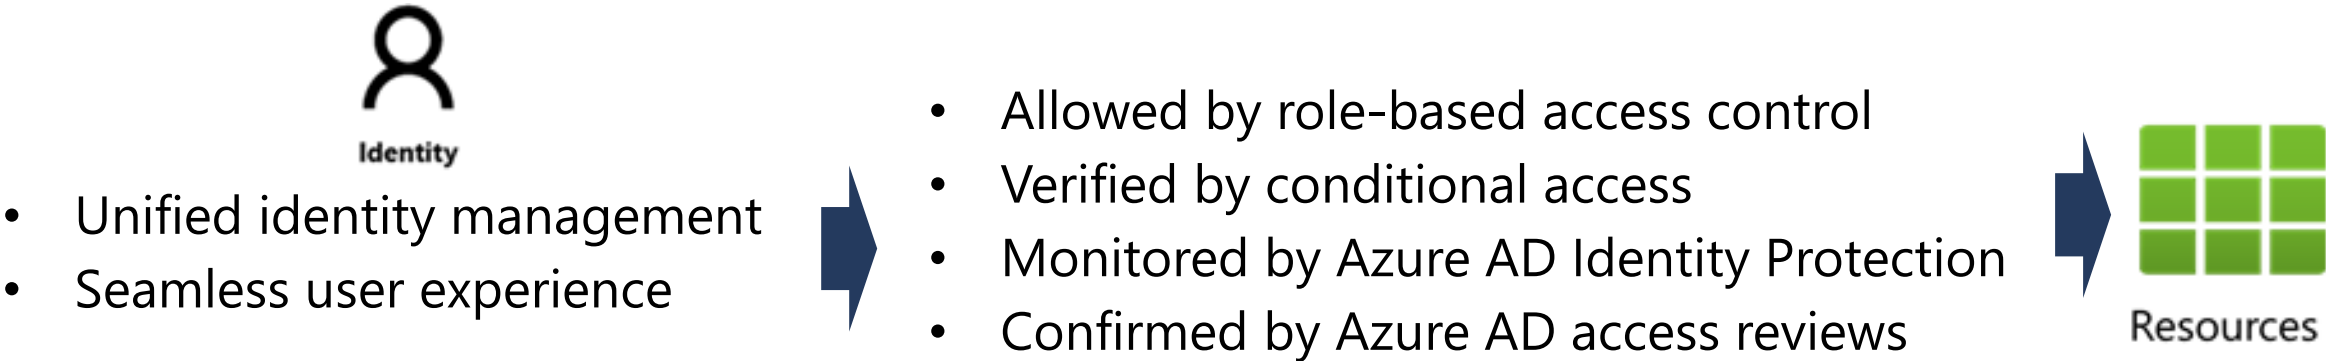

- Employee and partner user and roles
- Trusted and compliant devices
- Physical and virtual location
- Client apps and authentication method

On-premises & web apps

What is identity and access management

Identity

- Unified identity management
- Seamless user experience

- Allowed by role-based access control
- Verified by conditional access
- Monitored by Azure AD Identity Protection
- Confirmed by Azure AD access reviews

Resources

| If you need this	Use this
Provide identity and access management for employees in a cloud or hybrid environment.	Azure Active Directory (Azure AD)
Collaborate with guest users and external business partners like suppliers and vendors.	Azure AD Business to Business (B2B)
Control how customers sign up, sign in, and manage their profiles when they use your applications.	Azure AD Business to Consumer (B2C)

Design for Azure Active Directory

When to use Azure Active Directory

Azure AD is the Azure solution for identity and access management. Azure AD is a multitenant, cloud-based directory, and identity management service.

- Centralize identity management

- Establish a single Azure AD instance

- Use Azure AD Connect, or AD Connect cloud sync for hybrid identity sync

On-premises Identities

Azure Identities

Azure AD Connect

Active Directory Domain Services

Design for Azure AD Business to Business

When to use Azure AD Business to Business (B2B)

Azure AD B2B enables you to securely collaborate with external partners.

- Integrate with identity providers
- Use conditional access policies to intelligently grant or deny access
- Require MFA for guest users

On-premises Identities   Azure Identities   External Identities

Azure AD Connect

Business to Business (B2B)

Design for Azure AD Business to Customer

When to use Azure AD Business to Customer (B2C)

Azure AD B2C is a type of Azure AD tenant that you use to manage customer identities and their access to your applications.

- Integrate with external user stores

- Provide single sign-on access with a user-provided identity

- Create a custom-branded identity solution

- Use policies to configure user journeys

- Use progressive profiling to gradual collect user information

- Pass user data to a 3rd party for validation

Compare solutions (activity)

- Customers cannot be viewed by other users

- Users are managed in a separate Azure AD directory

- Users need to be able to self-signup for accounts

- Users manage their own profiles

- Users can come from SAML and WS-Fed based identity providers

Business to Business

OR

Business to Consumer
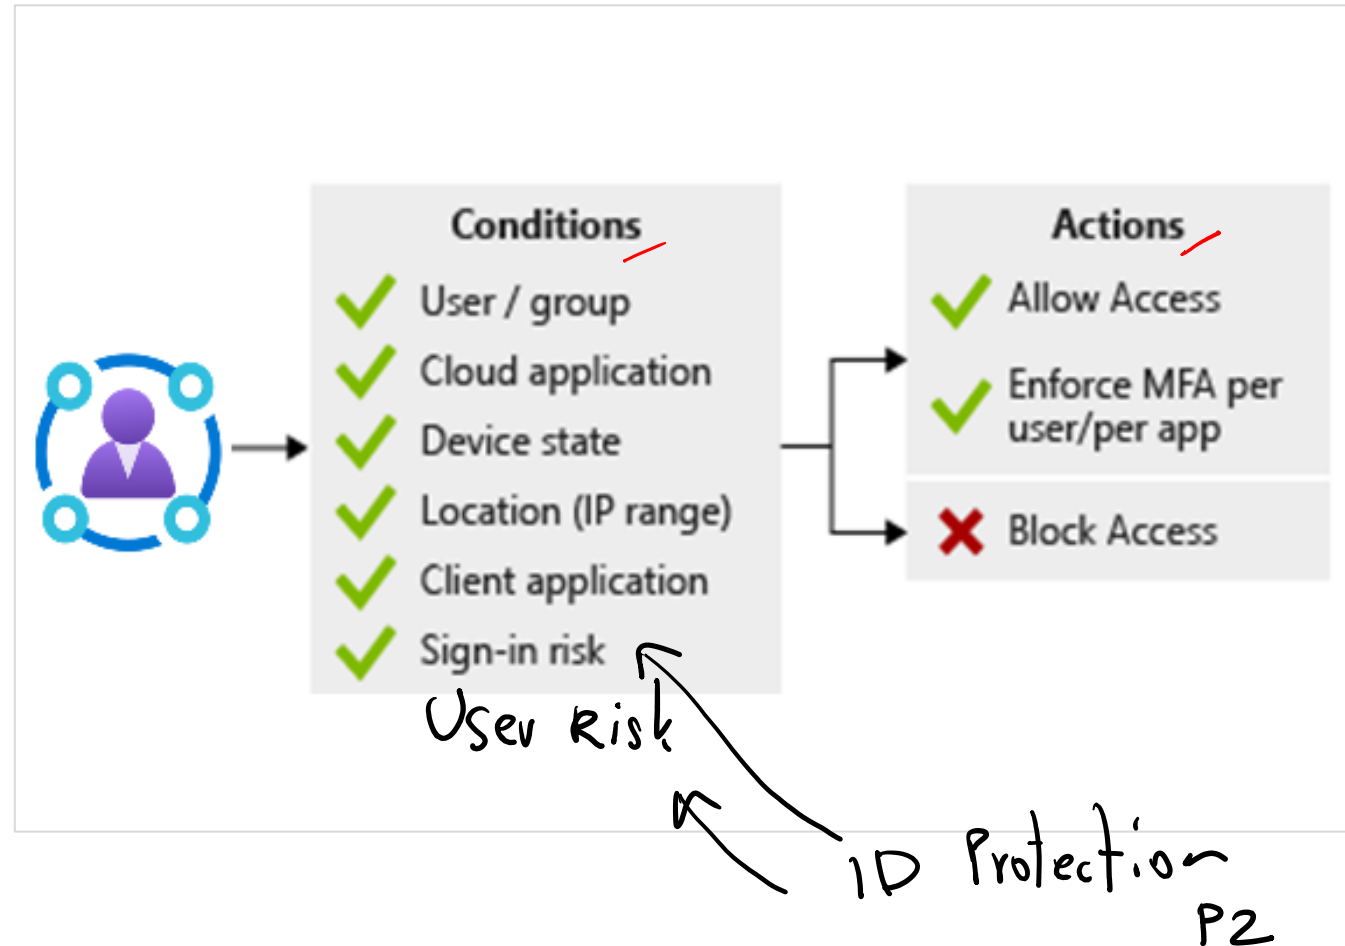

Design for conditional access

Break Glass Accounts

When to use conditional access

Conditional Access is an Azure AD tool that allows (or denies) access to resources.

- Use to enable multifactor authentication

- Require managed devices

- Access only approved client applications

- Exclude countries from which you never expect a sign in

- Respond to potentially compromised accounts.

- Completely block access

- Block legacy authentication protocols.

- Test using the report-only mode

Conditions
- ✔ User / group
- ✔ Cloud application
- ✔ Device state
- ✔ Location (IP range)
- ✔ Client application
- ✔ Sign-in risk

User Risk

ID Protection
P2

Actions
- ✔ Allow Access
- ✔ Enforce MFA per user/per app
- ✘ Block Access

Design for identity protection

# When to use identity protection

Identity protection is an Azure AD tool that automates the detection and remediation of identity-based risks.

- Configure the policies and actively review the results

- Set the sign-in risk policy to Medium and above and allow self-remediation options

- Set the user risk policy threshold to High

- Allow for excluding users - emergency access or break-glass administrator accounts

- Send data to Conditional Access or other security information and event management (SIEM) tool *Sentinel*
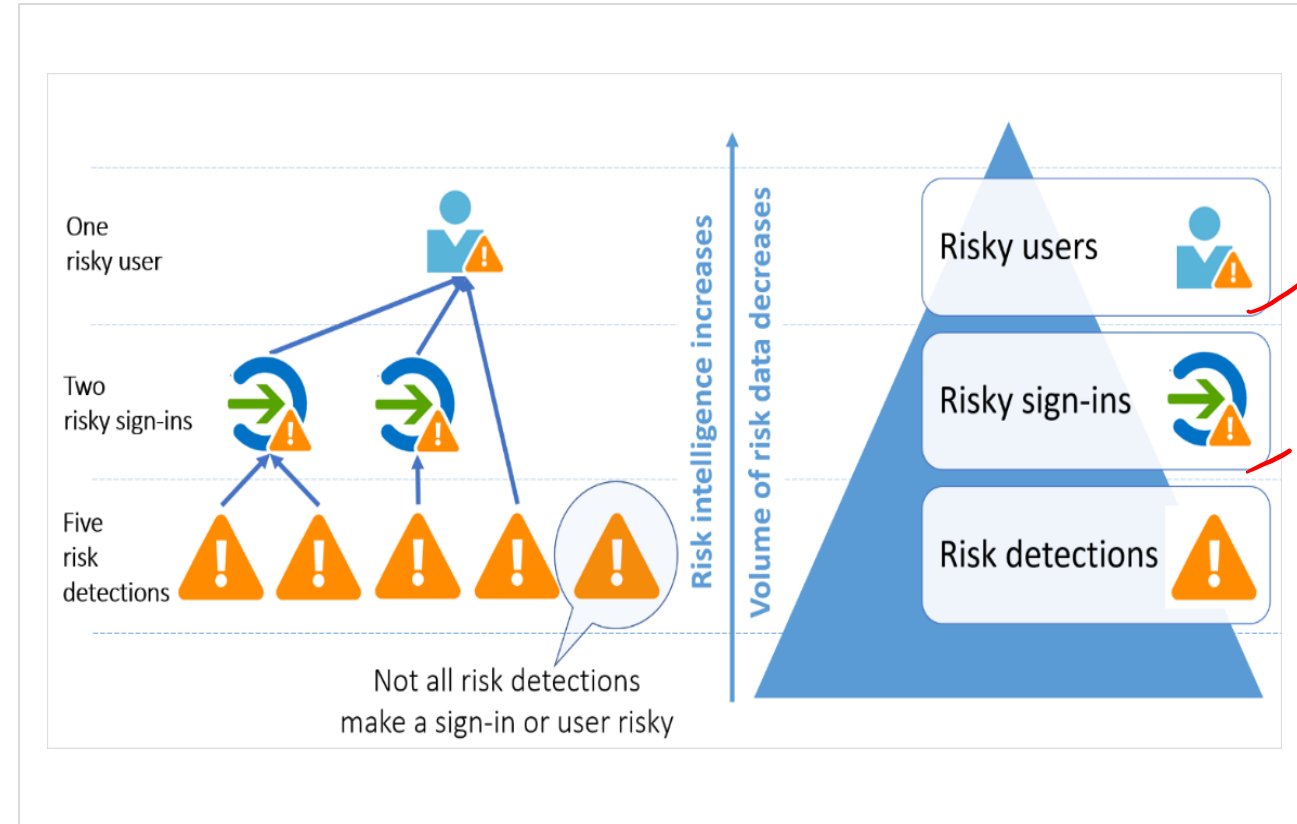

Design for access reviews
When to use access reviews

Access reviews are an Azure AD tool to review user access and ensure they should have continued access to resources.

- Determine the purpose of the access review

- Engage the right stakeholders

- Create an access review plan

- Determine who will conduct the reviews

- Decide who can self-attest access

- Determine what resource types will be reviewed

- Start small – pilot your plan – keep people informed

Report status to admin

App Registration

Appld

Password / Certificate

Design managed identities
Managed identities provide an identity for application authentication.

Handwritten annotations (top): Service Principal, Token, Cert, IMDS, VM → Managed ID (kein Password), System assigned, Contributor RG

Source
Target

I want to build an application using

- Azure VMs
- Azure App Service
- Azure Functions
- Azure Container Instances
- Azure Kubernetes Service
- Azure Logic Apps
- …

that accesses

Any target that supports Azure AD authentication
- Your applications
- Azure services (Azure Key Vault, Azure Storage, Azure SQL, …)

- The source is an Azure resource

- The target supports Azure AD authentication and Azure RBAC
- No credential rotation or certificate management

Handwritten annotations (bottom right): User assigned, User assigned

Select managed identities

Property	System-assigned managed identity	User-assigned managed identity
Creation	• Created as part of an Azure resource	• Created as a stand-alone Azure resource
Life cycle	• Shared life cycle with the Azure resource	• Independent life cycle • Must be explicitly deleted
Sharing across Azure resources	• Cannot be shared • Can only be associated with a single Azure resource	• Can be shared • Can be associated with more than one Azure resource
Common use cases	• Workloads that are contained within a single Azure resource • Workloads for which you need independent identities. • For example, an application that runs on a single virtual machine	• Workloads that run on multiple resources and which can share a single identity • Workloads that need pre-authorization to a secure resource as part of a provisioning flow. • Workloads where resources are recycled frequently, but permissions should stay consistent.

Select application service principals
This type of service principal is the local representation, or application instance, of a global application object in a single tenant or directory

Useful when Managed Identities cannot be used

Authentication is performed by the application using a secret or certificate

Often used to authenticate external applications to Azure resources
Best practices for requesting permissions

When building an app that uses Azure AD to provide sign-in and access tokens for secured endpoints, there are a few good practices you should follow.

When registering an application in AAD, consider business and security needs of admin consent versus user consent

Only ask for the permissions required for implemented app functionality. Don't request user consent for permissions that you haven't yet implemented for your application.

In addition, when requesting permissions for app functionality, you should request the least-privileged access.
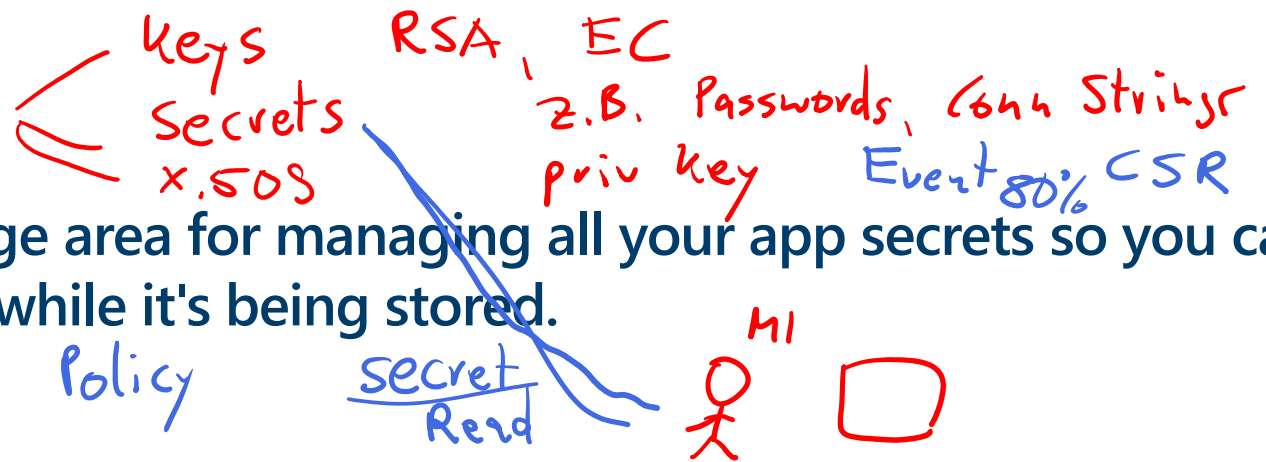

Apps should gracefully handle scenarios where the user doesn't grant consent to the app when permissions are requested.

Design for Azure key vault

Design for Azure Key Vault

Keys — RSA, EC
Secrets — z.B. Passwords, Conn Strings
x.509 — priv key   Event 80% CSR

Azure Key Vault provides a secure storage area for managing all your app secrets so you can properly encrypt your data in transit or while it's being stored.

Policy   secret Read   MI

Why use Key Vault?

- Separation of sensitive app information from other configuration and code, reducing the risk of accidental leaks.

- Restricted secret access with access policies tailored to the apps and individuals that need them.

- Centralized secret storage, allowing required changes to happen in only one place.

- Access logging and monitoring to help you understand how and when secrets are accessed.

- Implementing Customer Managed Keys for Azure services

When to consider multiple Key Vaults:

- RBAC vs Policies

- Performance
- Region

Case study and review

Case Study – Authentication and authorization

1. A company acquisition will add 75 employees – new user accounts

2. New employees are in different geographic regions – new identity protection policies

3. New application with a SQL database – access solution

Summary and resources

Check your knowledge	Microsoft Learn Modules (docs.microsoft.com/Learn)
	Plan, implement, and administer conditional access
	Plan, implement, and manage access reviews
	Create custom roles for Azure resources with role-based access control
	Enable secure external collaboration for your applications with Azure AD B2B
	Enable secure external access to apps for external users with Azure AD B2C
	Configure and manage secrets in Azure key vault
	Manage secrets in your server apps with Azure key vault
	Authenticate apps to Azure services by using service principals and managed identities for Azure resources
